

CSSD: Epidemiology and Control

Epidémiologie et Contrôle

J M Thresh

Formerly WACRI / EMRS / NRI

Epidemiology

Epidémiologie

“The study of disease in host populations”

“L'Etude la maladie dans la population d'accueil”

Epidemiology: A Quantitative Science

Epidémiologie Une Science Quantitative

- Disease prevalence/severity
- Means of spread
- Temporal patterns of spread
- Spatial patterns of spread
- Rates of spread
- Sources of inoculum
- Alternative hosts
- Crop loss

CSSD Epidemiology: Sources of Information

CSSD Épidémiologie Sources d'Information

Detailed long-term observations

- Farmer plantings
 - e.g. Old Station, Tafo
 - Koransang and elsewhere, Gh.
 - Koroboto, Nigeria
- Block plantings, Ghana
- Research trials
 - Planned experiments: Gh./Nig.
 - BRT, Ghana
 - Coppicing trials: Gha./Nig.
- Field maps/observations
 - Survey teams Ghana/Nigeria

Planned Experiments

Expériences Plannifiées

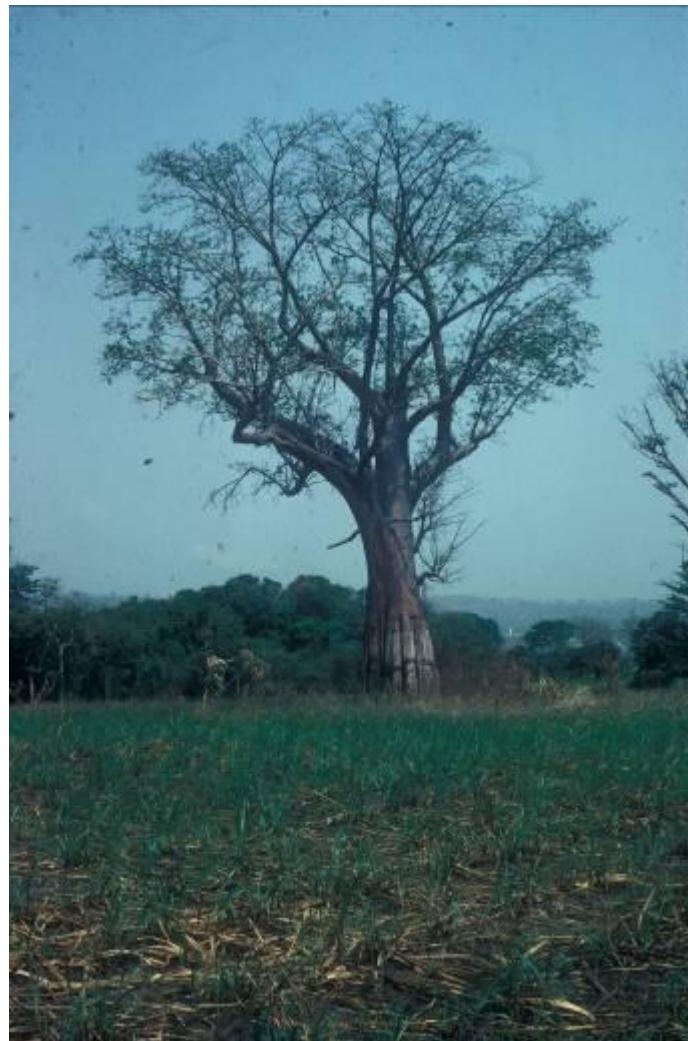

- Rate of Spread
- Effect on yield
- Mild strain protection
- Evaluation of resistance
- Barrier crops
- Effectiveness of insecticides

Sources of Infection

Expériences Plannifiees

- NOT seed
- Indigenous tree hosts
- Cacao (plantation/abandoned)
- Herbaceous hosts?

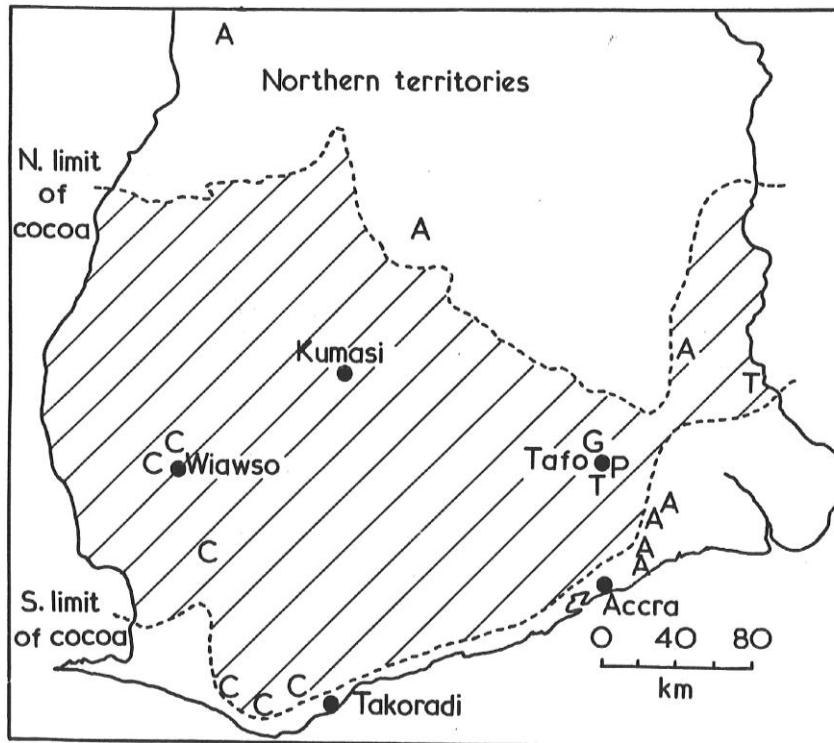

CSSV: Indigenous host Baobab(*Adansonia digitata*)

Silk cotton (*Ceiba pentandra*)

CSV in Indigenous Forest Trees in Ghana

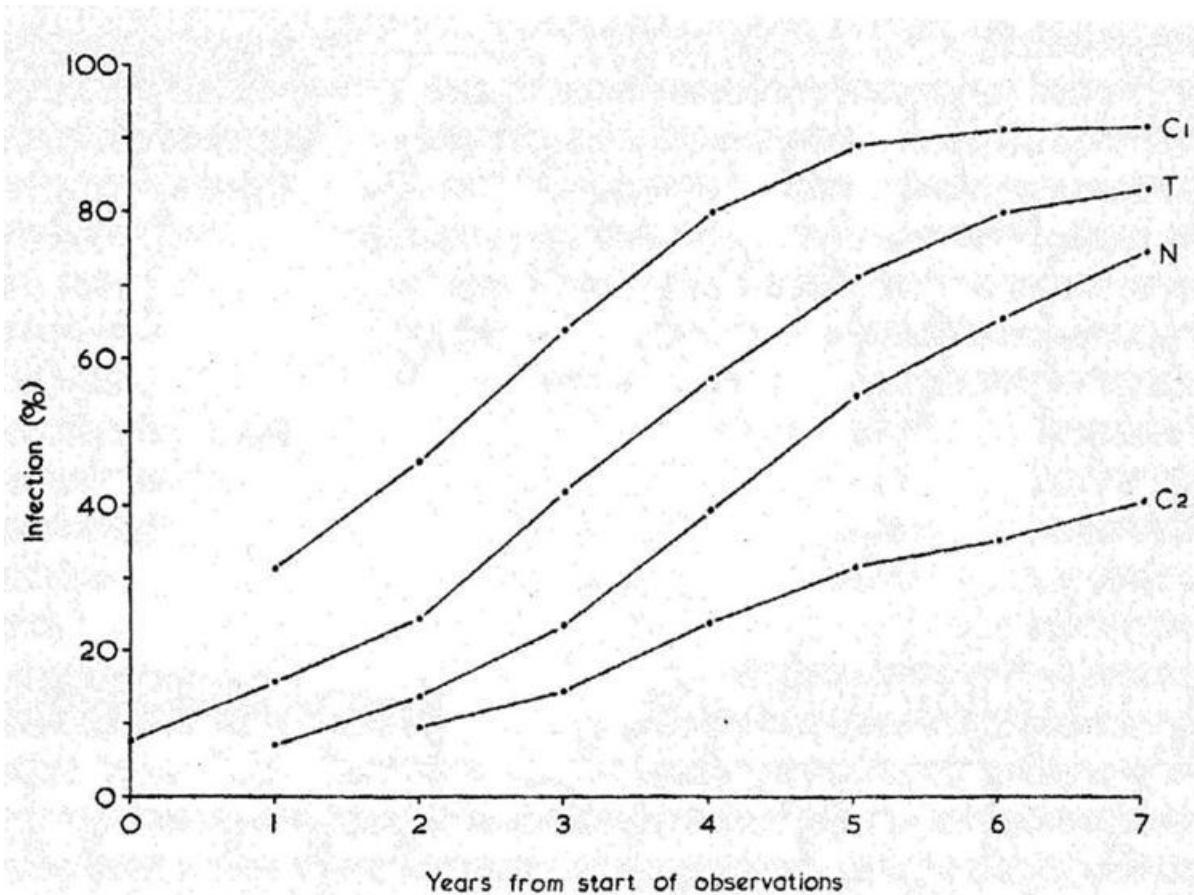

Naturally infected :

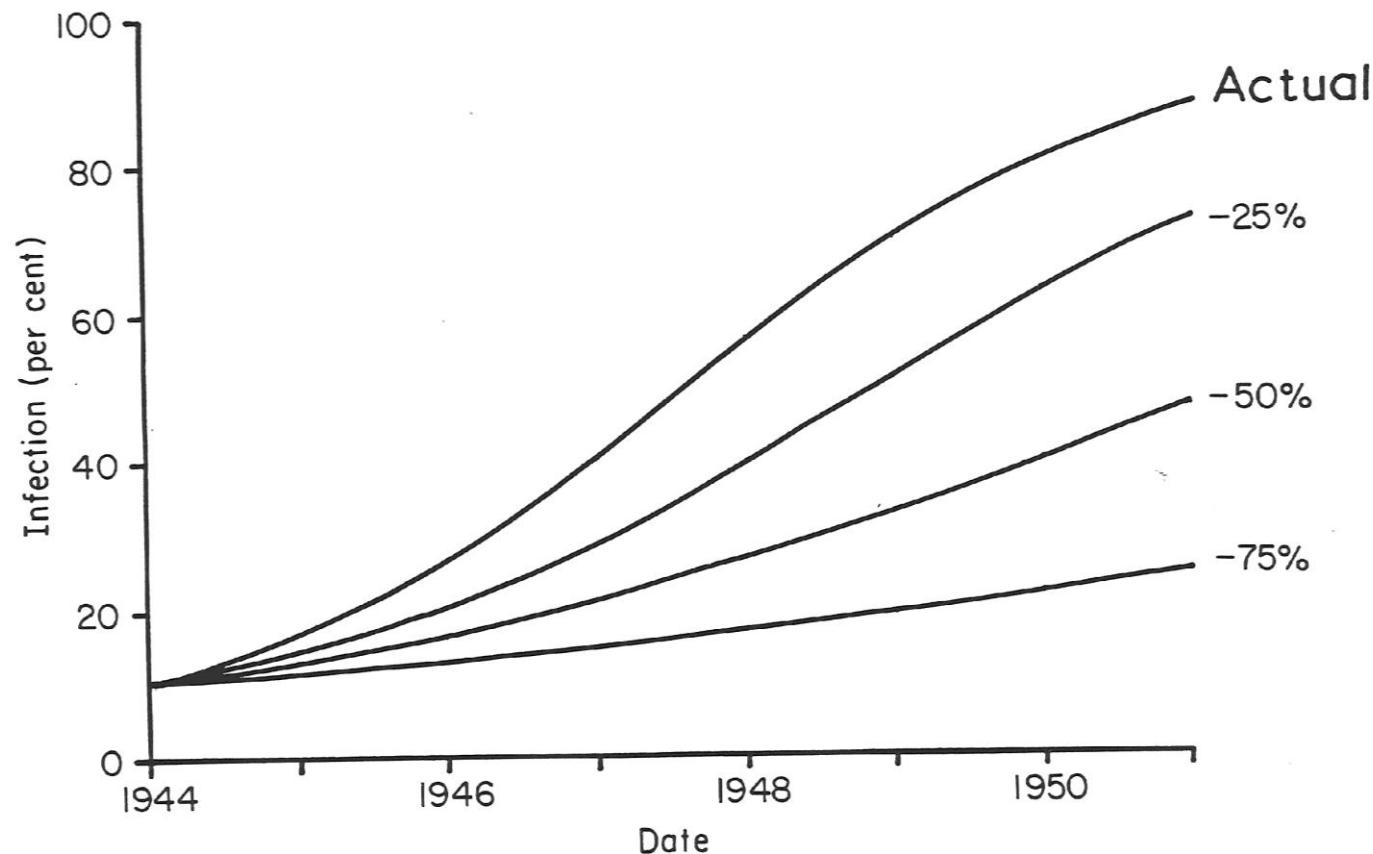

P	Ceiba pentandra	A	Adansonia digitata
T	Sterculia tragacantha	C	Cola chlamydantha
		G	Cola gigantea

Temporal Patterns of Virus Spread

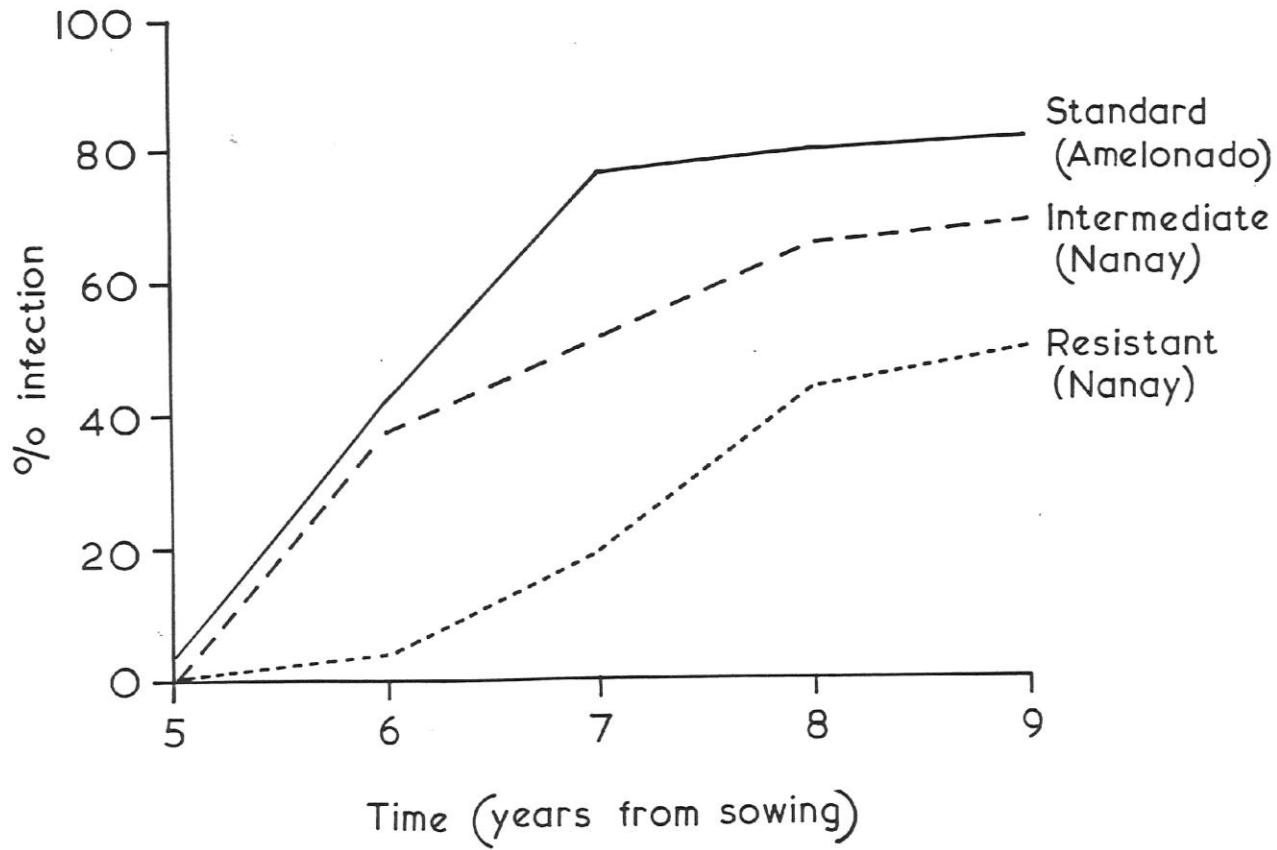

CSSD: Disease progress curves: Nig./Gh./Trin. Courbes Qui Illustrent La Progression De La Maladie

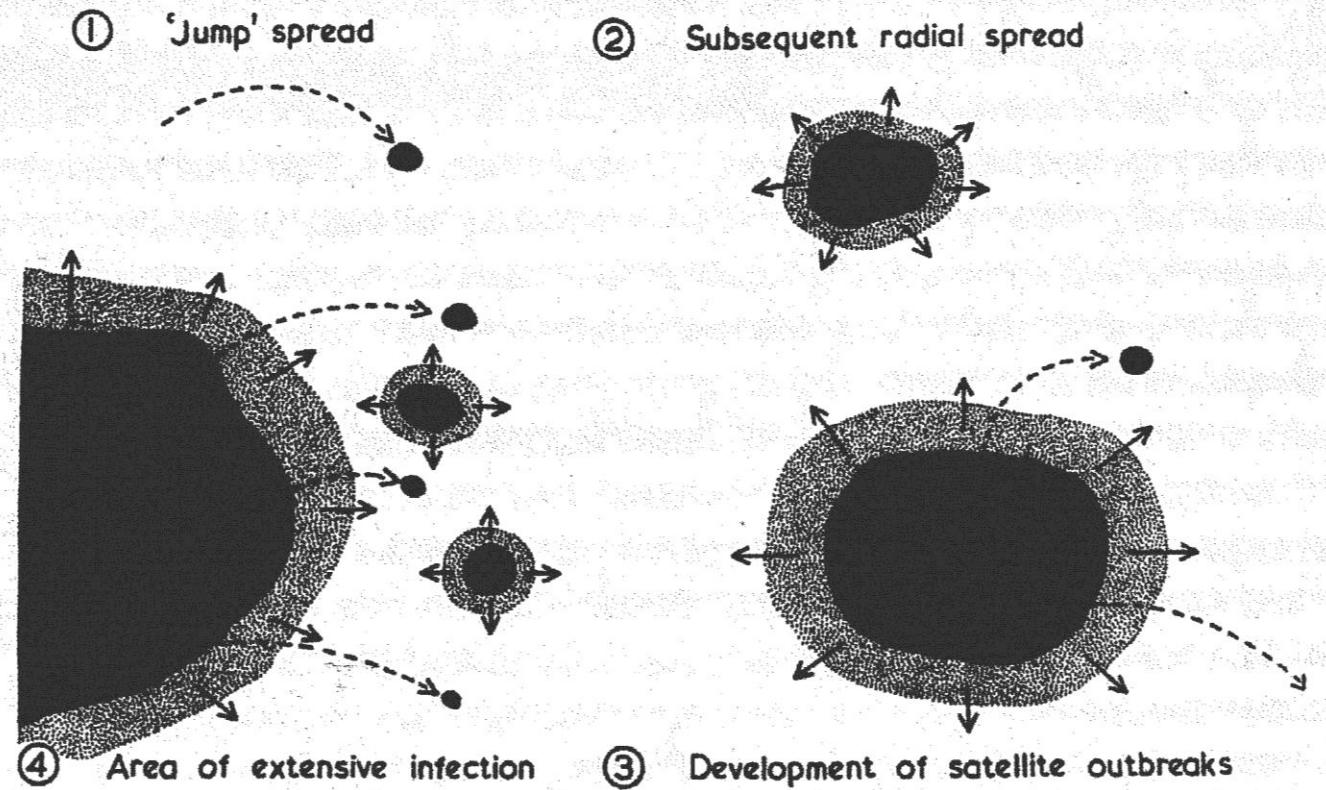

Mealybug-transmitted cocoa virus in Trinidad: Spread at different rates

Spread of Cocoa Swollen Shoot Virus in Ghana (Kenten & Legg 1971)

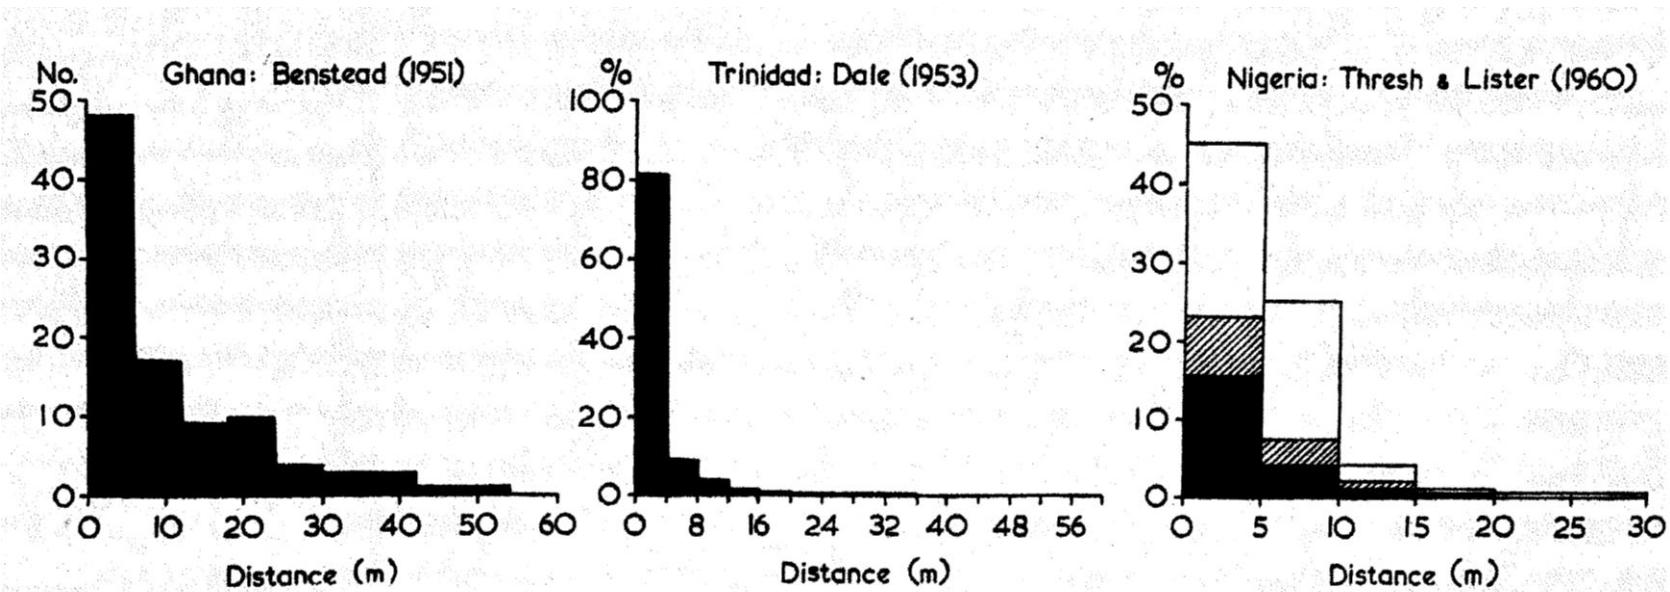

CSSD: Pattern of Spread Motifs de Progression

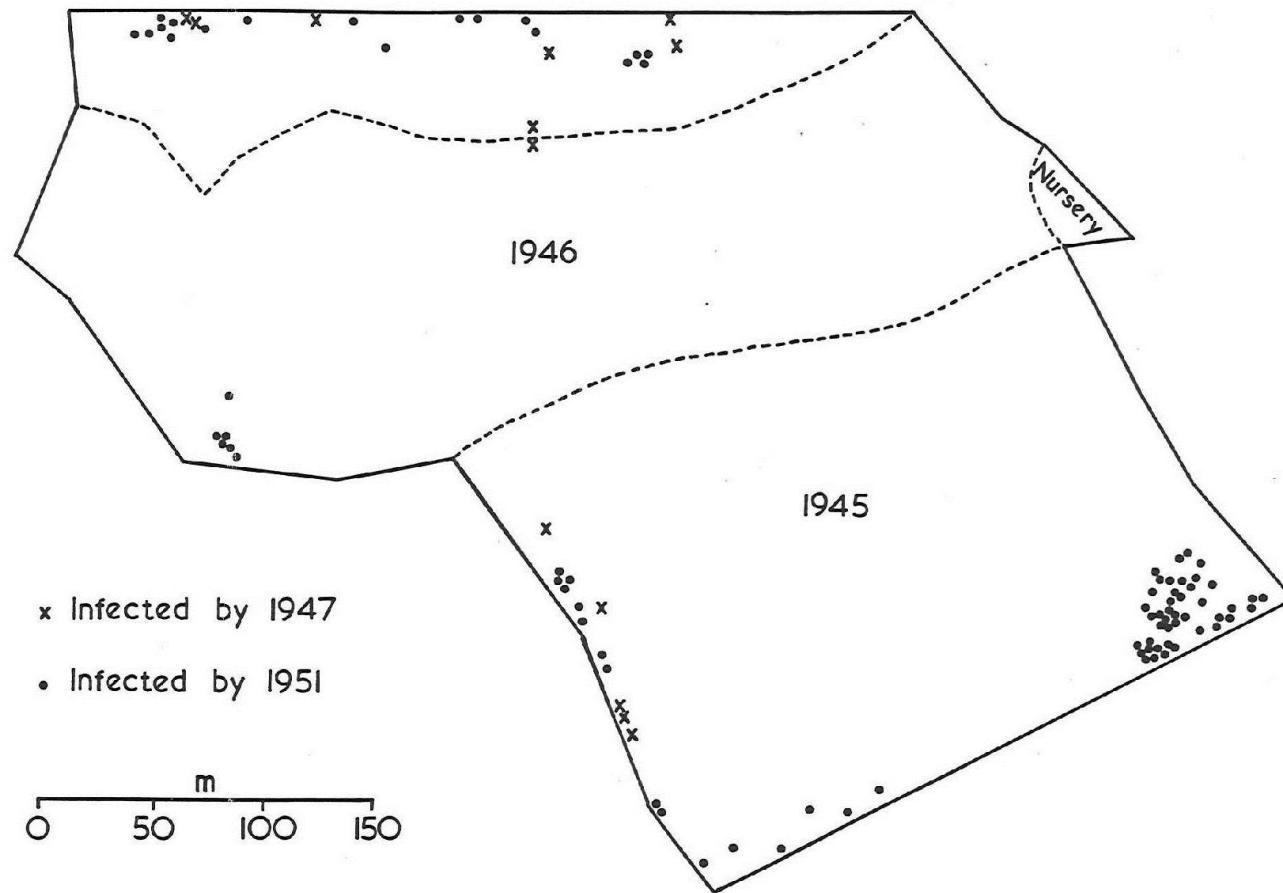

CSSD: Gradients of Infection

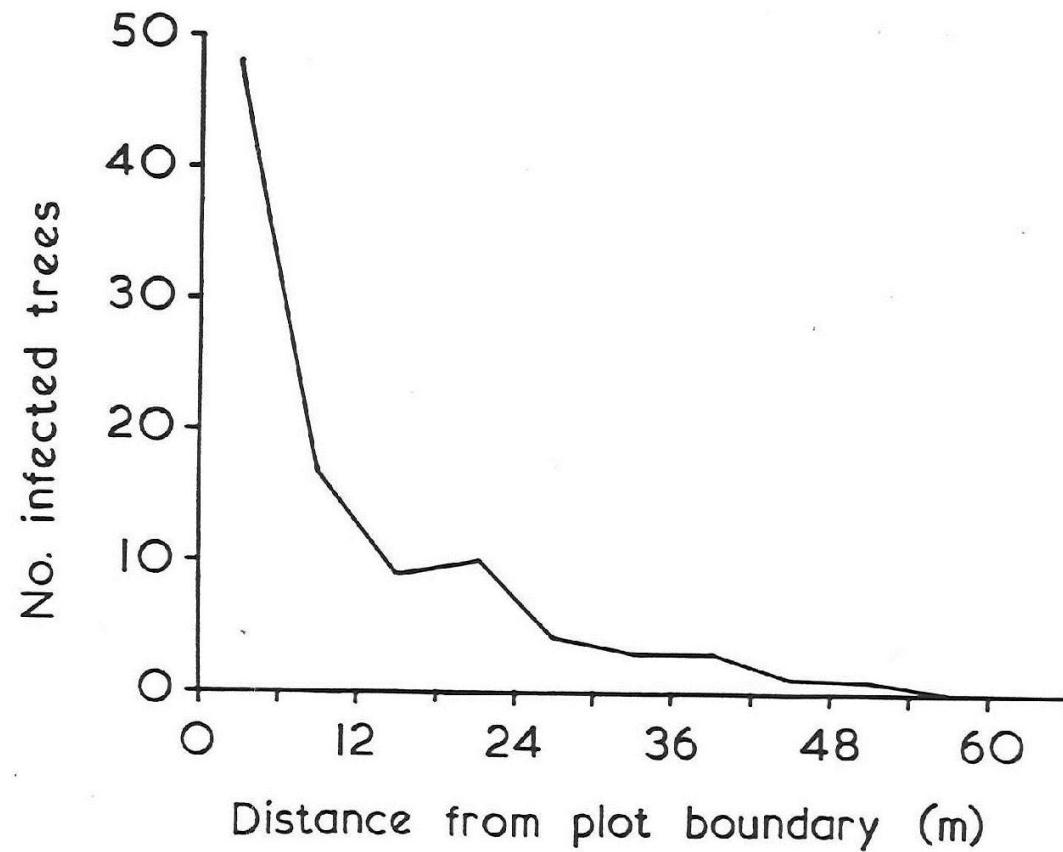

CSSD: Gradients de l'Infection

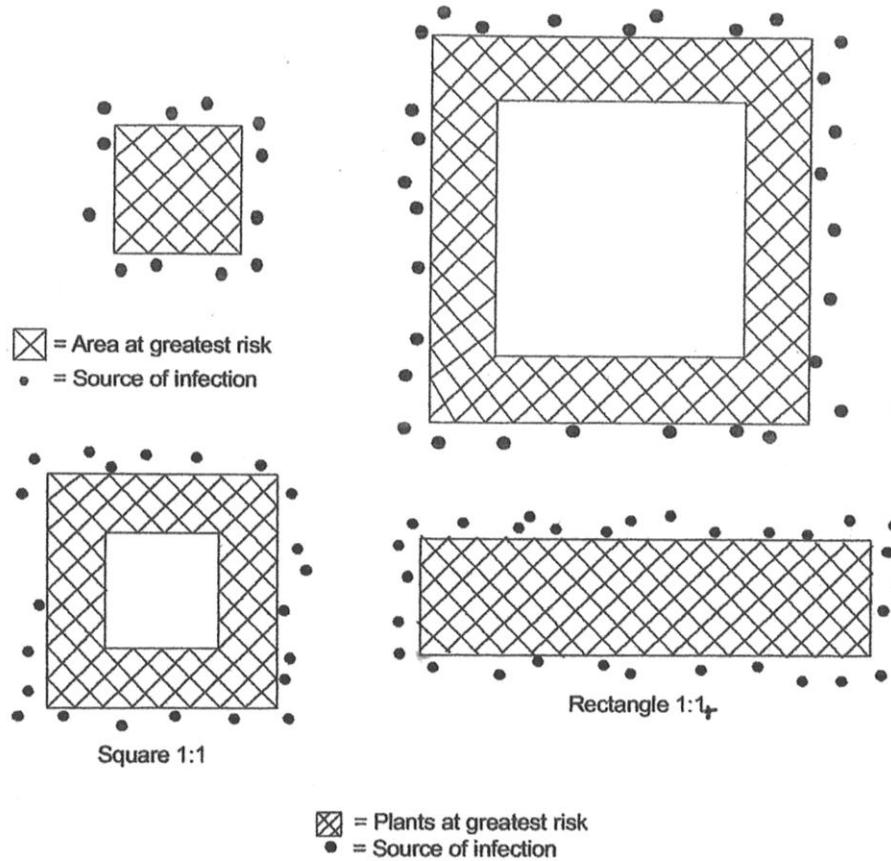

Infection in 1945/1946 Adonkwonta Block Planting

Cocoa Swollen Shoot Disease: Adonkwonta 6 years after re-planting

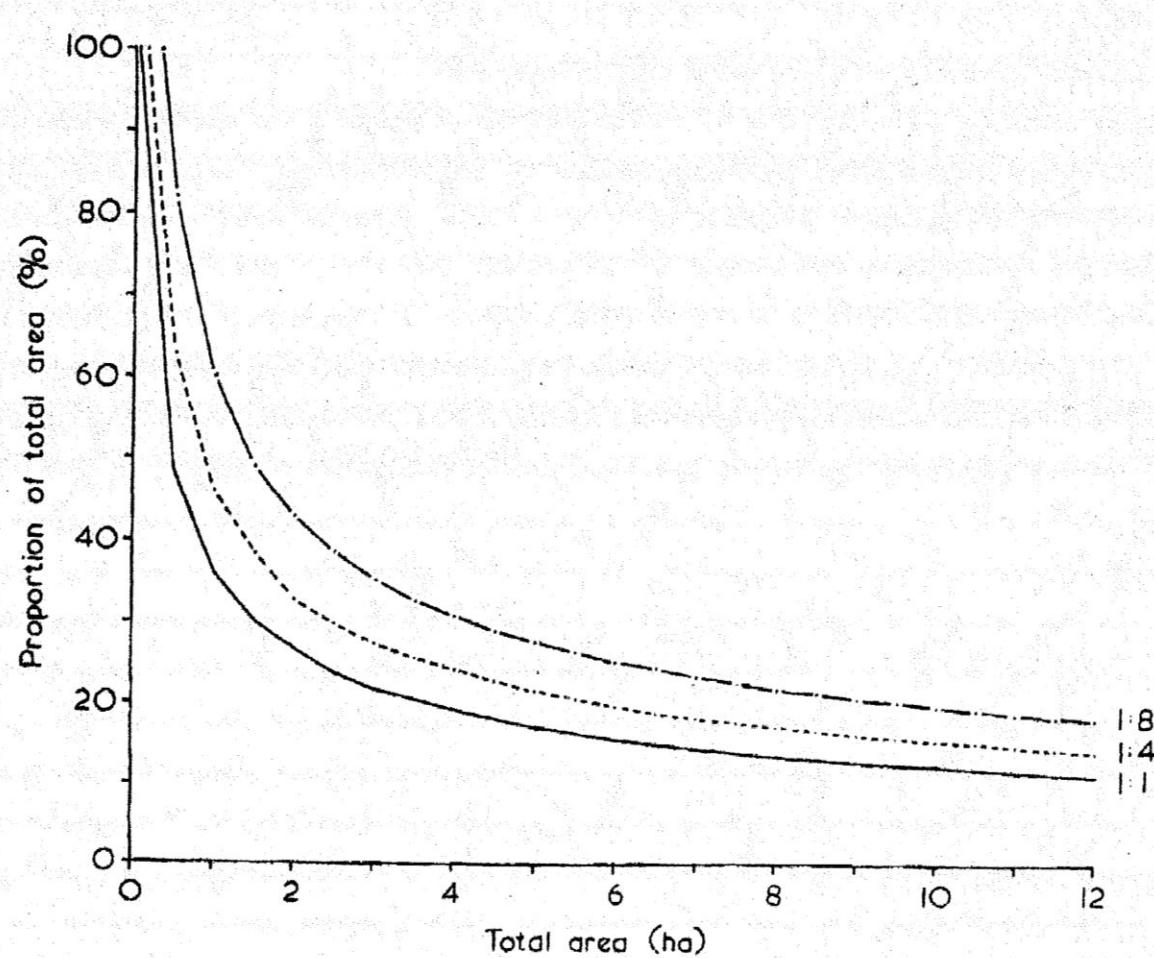

Influence of Plot Size and Plot Shape

The influence of plot/field size (top) and shape (bottom) on virus spread from surrounding sources of infection.

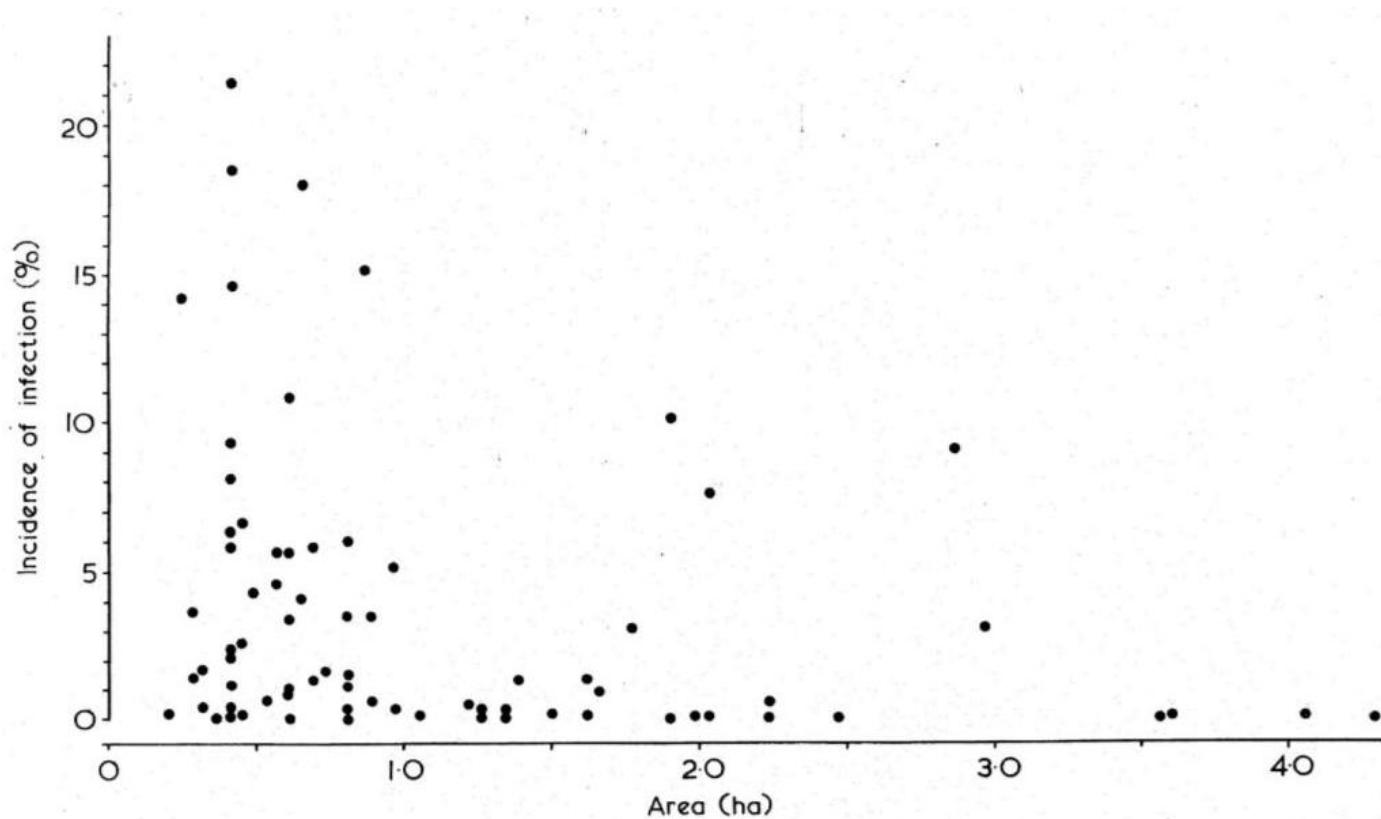

Plot margin as percentage of total area

Marges de tracé en pourcentage de la superficie totale

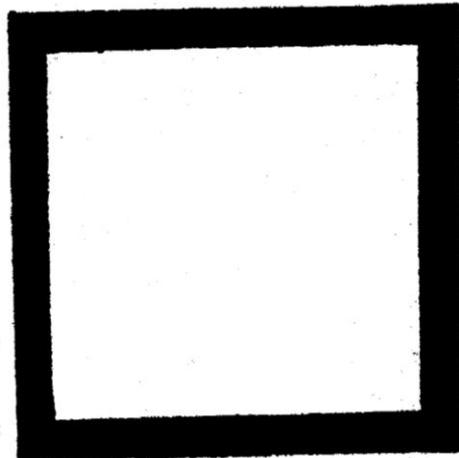

Incidence of infection in relation to plot size

Incidence de l'infection par rapport à la taille de la parcelle

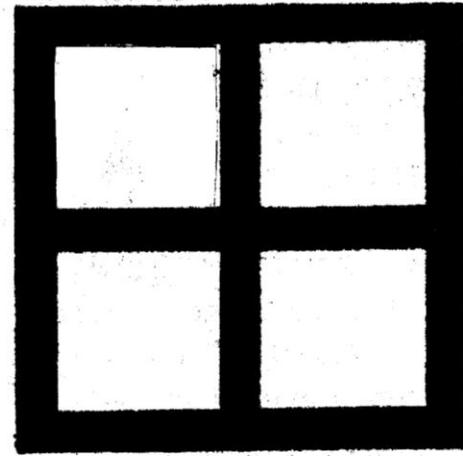

Possible Arrangement Of Barrier Crop Or Unplanted Area

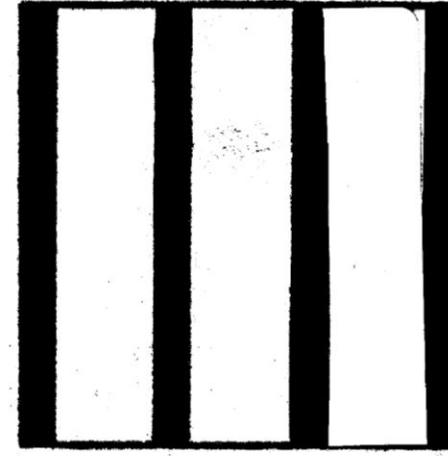

Arrangement Possible D'une Plantation Agissant de Barriere ou Alors d' Une Zone Non Ensemencee

Epidemiology: the Crucial Findings

Epidémiologie: Les Découvertes Cruciales

- CSSD is a "crowd disease" - "one that does not spread far in any considerable amount"
Therefore amenable to control by eradication
- Trees at margins of plantings are at greatest risk

Epidemiology: the Crucial Findings

Epidémiologie: les conclusions cruciales

- Nearby sources of inoculum are greatest threat
- Plantings should be compact and large
NOT small or of irregular shape

Epidemiology: the Crucial Findings

Epidémiologie: les conclusions cruciales

- "Quantitative" (partial) resistance highly beneficial and should be deployed

Conclusion

CSSD can and should be controlled.

CSSD Peut et Doit être Contrôle

However, this is only possible if control measures and cropping systems are based on sound epidemiological principles
